I have some difficulty when I do the floating exercise:
- When elements are floated, parent containers often collapse because they do not recognize the floated children's height.
- Floated elements can overflow their parent containers, causing layout issues.
- Floats rely on the order of elements in the HTML. Changing the layout requires changing the HTML structure.
- Floats do not provide built-in vertical alignment.
- Creating multi-column layouts with floats can be complex and requires careful calculations of widths and margins.
